

Cancer is a complex disease that involves an interplay of genetic and environmental factors. It is the second leading cause of death worldwide, with over 10 million new cases being diagnosed each year. Despite significant progress in understanding cancer biology and developing new treatment strategies, the disease remains a significant public health challenge. It is estimated that one in every three deaths globally is now due to cancer, with the incidence of cancer increasing worldwide due to population aging and improvements in diagnostic technologies.

Oncologic National Academies of Sciences, Engineering, and Medicine 2018-06-25 It is an era of promises advancing in cancer research, and there are considerable gains in our understanding of the genetic factors involved. Researchers now know that cancer in not a single disease-essentially subfields exist with different origins, risk factors, genetic mutations, behaviors, and progressions. However, potential barriers have been improved towardsGenerating Improvement in the prevention, early detection, treatment, and management of colorectal cancer. Failure to significantly improve mortality and morbidity during the past several decades is likely due to several factors, including the lack of research being performed by specific disease subspecialties, lack of detection methods for early diagnosis of the disease and increased proportion of late-stage diagnoses.

Determining the Proportion of Early-onset Colorectal Cancer that is Potentially Preventable.
